1. Basic Synthesizer Theory

A "synthesizer" is an electronic instrument which utilizes changes in voltage to effect changes in tone color (waveforms), intervals (frequency) and volume (amplitude) permitting the player to freely create desired sounds.

First of all we must set forth certain basic terms which clarify how synthesizer principles compare to the basics of previous electronic musical instruments:

Previous electronic musical instruments created tone color in the following two ways, for the most part.
1) Composite Voicing (harmonic synthesis)
2) Format (filter) Voicing

The system is outlined in the following block diagram:

1. Tone Generator System
2. Keying System
3. Voicing System
4. Expression Pedal System
5. Amplifier System
6. Speaker System

(1) The tone generator system produces all the signals (notes) used in the organ.
(2) The keying system controls the signals through electronic gates operated by the keys on the keyboards.
(3) The voicing system shapes the signals to represent various instruments or voices. The organist selects which voice he wants the signals to represent by operating tabs or tone levers on the control panel.
(4) (5) (6) These operate in the same way in the synthesizer system.

The diagram below illustrates the basic construction of the synthesizer system:

```
Frequency controlled by voltage.

KEYBOARD ----> V.C.O ----> V.C.F ----> V.C.A ----> A.M.P

Voltage
---- Signal
Voltage shows the key is on.

EG-VCF

EG-VCA

ADSR
```
(1) VCO (Voltage-Controlled Oscillator)

The VCO is an oscillator which creates waveforms by using voltage to control oscillation frequency. In most cases the waveform is a complicated one, incorporating many short sawtooth and pulse wave formations.

In addition to the voltage from the keyboard, other voltages can also be fed to the VCO, from other oscillators.

In the case of ultra-low frequency sine waves, a vibrato effect is created. On the other hand, the addition of square waveforms, depending upon the voltage, creates "poo-pi-poo-pi" and other types of sounds.

(2) VCF (Voltage-Controlled Filter)

This is a tone color circuit which adjusts the filter performance according to voltage.

The VCF changes the tone color (waveform) of voice signals sent from the VOC by adjusting the cut-off frequency and resonance according to changes in voltage.

Previous electronic organ tone color circuits worked by first using input signals in chords, with no other way to adjust except by using filters. In the synthesizer, voltage controls the operation of filters which can work with individual tones; in this way a filter circuit which can decide the output wave with fixed harmonics regardless of key is created.

(3) VCA (Voltage-Controlled Amplifier)

This circuit used voltage to control the degree of amplification.

The voltage works here to adjust changes in the rise and attenuation of signals coming from the VCF, as well as affecting attack and sustain effects.

(4) ADSR (Attack, Delay, Sustain, Release)

The conventional ADSR circuit changes the envelope in the following way, feeding the envelope to the VCF and VCO to change tone color and volume. In the Yamaha system, however, this part is already reduced, making use of EG-VFC and EG-VCA circuits.

```
A : ATTACK TIME
D : DELAY TIME
S : SUSTAIN
R : RELEASE
```

(5) EG-VCF (Envelope Generator VCF)

In the Yamaha synthesizer the ADSR is designed on the basis of the EG-VCF envelope, as the figure below illustrates.
This envelope exists to create tone color changes while assuring tone color stability throughout the interval that a key is held down (except for rising and falling). For this purpose, the key On condition is taken as 0 standard basis and the envelope revolves around this standard as its center.

The EG-VCF can change or adjust the following items within the envelope waveform:

AL : Attack Level
1DT : First Decay Time
2DT : Second Decay Time
IL : Initial Level

Consequently, the VCF can also provide changes in tone color during voice signal rise and fall, according to changes in the EG-VCF envelope.

(6) EG-VCA (Envelope Generator VCF)

The EG-VCA can affect the following changes, as shown in the illustration below:

AT : Attack Time
2DT : Second Decay Time
1DT : First Decay Time
SL : Sustain Level

*Table 1: Terminal: K1 Digital Voltmeter Input Impedance: over 100KΩ*

The Yamaha solo synthesizer creates proportional frequencies through the varied voltages applied to a single voltage-controlled oscillator by each key.

The VCO, which is controlled by the input voltage, it is an oscillator which controls the relation between input voltage and output frequency.

The voltage at terminal K1 in Fig. 1 is 4.00V at C5, 2.00V at C4, 1.00V at C3 and 0.50V at C2, so this ratio is clear. From OP1 in Fig. 1 a standard +4.00V ± 0.01V is supplied. At the same time, however, the input of OP1 is a tuning voltage input, and can be used for ±100 Cents changes. First adjust the UK terminal for +4.00V ± 0.01V (use VR1B1K). Next, check at VRB500Ω on the SM circuit board that C4 is +2.00V ± 0.01V and that all other intervals are correct according to Table 1. At this time ability absolute accuracy and input impedance of the D.C. volt meter should be less than 0.5%, with an input impedance of over 100KΩ. An error of 0.055% in the voltage will cause a pitch variation of 1 Cent. For example, 0.055% of 4.00V is 2.2mV.

When adjusting each key, connect the fixed resistor 1.8KΩ (allowable error: ±0.5%) between K1 and E on each ckt board, then adjust for 4.00V – 2.127V (C5 – C♯4) consulting Table 1. In actual organs, at lower intervals this voltage may well be on the low side.

(2) Key Voltage Buffer Amp and Keying Circuit

![Circuit Diagram](image)

**Fig. 2**
Impedance is changed by OP3 to protect against drop in each key voltage, providing stable pitch voltage to VCO II.

The OP1 (operational amplifier) serves to feed the voltage of each key into non-inverting input.

DC voltage created by OP3 is fed to the SK circuit board Schmitt circuit and to FET 1 in Fig. 2. The SK circuit board creates the delay pulse required when the keyboard is switched on or off.

The above pulse is fed from SK circuit board GI terminal to FET 1 with a slight delay when the switch is turned on, in order to avoid key switch chattering. Keyboard voltage travels through FET 1 or R1 (when FET 1 is off).

(3) VCO II (Voltage Controlled Oscillator II Module)

Fig. 3 illustrates the VCO II module. The sawtooth wave frequency responding to input voltage is created in the VCO. Each terminal input and output is also noted. The model adjustment method requires setting to transposition normal.

Check that the voltage at the U0 terminal (Fig. 2) is the same for terminal VI when C4 is pressed; also check that this voltage is being fed to VC2.

1. Check for the determined ±15V. (DC power supply voltage)
2. Check that a normal pulse is fed to terminal K when the key is pressed and released.
   There is an FET gate in VCO II; the signal passes from SK circuit board K terminal to the VCO II K terminal.
3. A P-P 3.0±0.3V (1046Hz±2% or ±1%) sawtooth wave is created at A02 and A0 terminals. In this case, however, an oscilloscope frequency counter is required, then the tone can be checked and adjusted in the same way as an Electone. If the VC2 input voltage is not proper under ordinary conditions, adjust with an added capacitor.
   If further adjustment of the portamento is desired it can be accomplished by inserting a VR between VC3 and VC1 of the VRII section.
Fig. 4

Fig. 4 illustrates the waveform change circuit which permits changes in the sawtooth waveform width by short waveform transformations. It would be best if the input waveform shown in part B of the figure was changed to the width of the Tr1 action point.

However, the duty cycle ratio can be changed according to changes in the voltage of the VR connected at PW between +10V and E.

This is called “pulse width.” The ratio is 50%–90%. The VCO creates a sawtooth waveform, while this waveform change circuit creates a square waveform. In order to have a waveform appropriate for the tone color, these two forms are used separately.

(5) Auxiliary Gate Circuit (For preset double and reed tones)

When the transformed square wave and the sawtooth waveform which is VCO II output are used together, the FET 3 gate is controlled by the DR terminal, this is used for preset double and reed only.

AO
E F -15

Fig. 6

Fig. 6 shows the connections between VCF: LPF and VCF: HPF. VCF is composed in the same way as VCO: of a molded circuit, so resistance to temperature fluctuations is outstanding. VCF: LPF can be thought of as a flute tone color-type waveform change filter. The various VC2 terminals of VCF feed voltage which is changeable according to touch and exp. controls, etc., providing cutoff frequency. The various fixed voltages from the preset tones and resonance VR are fed to VQ1. The resonance controls the cutoff wave oscillation point by ZETA: cutoff frequency resonance point of the lowpass filter. The VCF: HPF, like the VCF: LPF, is a voltage-controlled circuit which affects changes in filter characteristics. VC2 feeds in VCF EG, WAH (touch control) and Exp. control voltages. VC1, which also changes input frequency during octave up stages, feeds in varied voltage to change filter characteristics. VQ1 exists to vary filter cutoff points. AO output is fed into VCA.

(7) VCA (Voltage Control Amplifier)
The VCA circuit is illustrated in Fig. 7-1. VCF output is fed to OP2 as shown in Fig. 7. OP2 is a current control operation amplifier; its gain changes according to the current fed to terminal 5. The OP 1 input signal controls OP 2 via envelope voltage input from the SK circuit board VAO terminal. The OP 2 output which has been thus controlled either passes through the FET1 or (for harpsichord and pizzicato violin only) creates (−) voltage at the FET1 gate, thus passing through capacitor C only and working with the CR bypass filter to cut bass click noise. OP 3 is also a current control type OP amplifier. According to touch control and exp. control voltage inputs from 1 and 2 Tr2 emitter potential rises, causing current to flow between (5) and (E) in OP 3. The SC terminal can control via terminals 1 and 2 when they are used by feeding −15V to the FET2 gate and thus shutting the FET2 off. However, if terminals 1 and 2 are not used, the FET2 is normally on, thus supplying a fixed current to terminal 5 of OP 3 via the resistor. Thus a buffer amp input is provided via total VR. Output waveform is shown in Fig. 7-1.

![Fig. 7-1](image)

(8) Output Amplifier and Click Noise Avoided Circuit

Voltage Input to Control Click Noise During Harpsichord and Pizzicato Violin

From Total VR

Complete Output Terminal Q01

+15V

![Fig. 8](image)

Fig. 8 shows the output amplifier circuitry. When harpsichord or pizzicato violin signals mixed with the input signal, in order to control click noise (−) voltage is supplied, shutting off the FET. The signal passes through the capacitor and resistor, effectively cutting out click noise. Terminal 01 output impedance is approximately 600Ω, so 0dB output voltage is provided.

The circled circuit in Fig. 8 serves to avoid click noise when the power is switched on. At this time the transistor switches on to short all output signals; then the capacitor charges and the transistor switches off for normal output signal.
9) VCF EG (VCF Envelope Generator), VCA EG

Fig. 9

Fig. 9 shows the VCF EG and VCA EG module circuits. When +10V is fed to the PC terminal, VCF EG takes 0 level as its center and rises to the + side, then lowers to create the output waveform at OF like that shown in Fig. 10-1. When −10V is fed to the PC terminal, a waveform converse to that shown in Fig. 10-1 appears as output at OF. Terminals AL, AT, 2D, IL, 1D and PC create voltage waveforms which match the tone color of the preset voltage inputs from the SP circuit board. These waveforms are fed to VC 2 of VCF, LPF and HPF as inputs, changing the filter sawtooth wave frequencies to create the various preset tone waveforms.

![Attack level](image)

Fig. 10-1

(10) Oscillator Types

9-1. Vibrato Oscillator

Fig. 11 illustrates the circuitry of the vibrato oscillator.
When the (-) terminal potential is less than the (+) terminal, current flows from C through the VR and resistor between 6 and 7. When the potential is higher in the (-) terminal, OP 1 output is reversed. (-) terminal potential becomes that of the (-) terminal and C discharges through the resistance between 7 and 6. When the (-) terminal potential drops lower than that of the (+) terminal, the original condition recurs. This back and forth motion in the (-) terminal creates a constant charge-discharge pattern in the capacitor, giving rise to a triangular waveform. Between 6 and 7 is a vibrato speed VR connected to SP of the SP circuit board. When the VR resistance is high, OP 1 frequency is low. By the action of the vibrato depth control voltage input at terminal 8 and the touch control vibrato depth voltage input at terminal 9, OP 2 gain is controlled. This signal is fed from the VB2 terminal to the various VC2 terminals of the VCF, LPF and HPF. Terminal 10 feeds the controlled signal from the WA terminals of the SP1 and SP2 circuit boards to VC2 on the VCF, LPF and HPF, thus acting as a control. This untouched signal is wah guitar vibrato.

9–2. Double, Reed Preset Tone Oscillator

This section works on the same principle as the vibrato oscillator: output impedance is lowered thanks to the FET. The vibrato effect is created by adding the signal from terminal 11 to the preset double and reed tones.

(11) Exp. In Buffer Amp, Touch Control Detector Buffer Amp

EC or TC: From Touch Control Cds

Fig. 13 illustrates the circuitry of the Exp. In control buffer amp and the touch control detector buffer amp. This amplifier serves to make the control voltage optional, and also to keep output impedance low. Input and output signals are unified, and (+) voltage appears at the output.

(12) Harpsichord and Pizzicato Violin Click Prevention Voltage Switching Unit

(+)-input is fed from HA and PV in Fig. 14, switching the Transistor on and reducing output resistance to -15V. When the voltage becomes negative a slight delay can be created by the capacitor, cancelling click noise in the PST switch.
Voltage Generator for Various Gate Pulse Circuits, Tone Bend and Pitch Bend Circuits
Fig. 15 shows the circuitry for the tone color basic oscillator which functions for the various gate pulse circuits, pitch bend and tone bend circuits and SP1 & SP2 circuit boards. Fig. 16 shows the pulse waveforms for the various terminals.

Keyboard voltage is fed to terminal KV. OP1 works as a transformation amp to differentiate between these outputs. It contains a rectifier circuit which changes the positive/negative pulses of the Tr1 output which passes through buffer amp OP2 into positive-only, then feeds them as input to one-shot multivibrator I and II. One-shot multivibrator I uses the Tr10, Tr11 delay circuit to feed delay pulses from terminal G1.

At the same time, the Schmitt trigger creates pulses like that shown in the figure by feeding the pulses created by Tr7 and Tr8, then delayed by Tr16 and Tr17, from terminal AG. The AG signal is fed to AG' and it passes to the pitch bend circuit P2. It then passes from the PB terminal as input to the VCOII VBI terminal. The waveform created by the Schmitt trigger circuit and the one-shot multivibrator of Tr5 and Tr6 passes from terminal K and is used to create the pulse shown in the figure, driving the gate circuit in the VCO II.

In order to feed the waveform created by VCA EG to VCA as input from terminal VA I, output is fed from VAO. However, when the key is first pressed turning the switch on, Tr27 is off, so the signal from VA I passes to VA 0.

When another key is pressed Tr27 goes on momentarily and the signal does not pass from VA I to VA 0. Previous control voltage to VCA is cancelled. Thus an integral circuit, composed of a 10KΩ resistor and 0.1μF capacitor, is formed to prevent click noise when a key is first pressed.

TB is a special output terminal for tone bend, fed by VCF LPF. The LC terminal is controlled by the attack bend intensity VR, thus controlling the TB output voltage.

OP7 is a basic voltage amplifier, supplying +10.6V to the SP1 and SP2 circuit boards. Therefore +10.6V is fed from the +10 terminal.

Fig. 6 Output Waveform at Each Terminal
3. Concerning Modules

In order to create temporal changes in pitch, waveform and volume these modules work by control from very small amounts of voltage.

Modules are made up of C, R, Tr and IC, etc. component parts, and in order to assure high reliability a composite resin filler is used. In distinguishing good and faulty modules there is a basic method to be used, described on the following pages.

1. VCO II (NE-10200) Voltage Controlled Oscillator

The oscillator frequency \((f)\), which is the tone source, is compared to control voltage \((E)\):

\[
f = KE \quad (K \text{ : fixed value})
\]

1. Sample Hold FET Test

During switch 2 the digital voltmeter should indicate \(2V \pm 30mV\).
During switch 1 the digital voltmeter should indicate \(0V \pm 2mV\).

2. Oscillator Frequency Adjustment
2-1. Zero Adjustment
Connect as shown in the figure, and set both switch 1 and 2 to condition 2. Adjust the exterior VR B1K so that the DVM indicates ±1mV. Then disconnect the DVM and set switch 2 to condition 1. Then, when the DVM is connected to terminal 14, the reading should be within the limits of $2V \pm 0.8V$ mV.

2-2. Oscillator Frequency
Use an oscilloscope to check that a sawtooth waveform of approximately 4V p-p is present at the output. Frequency counter reading should be 1060 ± 200Hz.

2-3. Output Waveform and Offset Voltage Adjustment
Adjust VR1 so that the oscilloscope shows a 4V=100mV sawtooth waveform. If a sliced waveform appears at the output at this time, adjust VR2 to the proper value.
Adjust VR2 so that DC offset voltage is ±100mV.

2-4. Vibrato
When switch 1 is set to condition 1 vibrato should appear on the oscilloscope waveform.

2-5. Output Waveform for Audio
Connect the oscilloscope to (10) and check that the waveform is 3V ± 0.6V p-p.

(2) VCF-LPF (NE-10400)
VCF: Voltage Controlled Filter
LPF: Low Pass Filter

--- Diagrams and Text ---

- Oscilloscope: Click waveform should be less than 250mV p-p.
- Oscilloscope: Rise and fall of the 100Hz short waveform should be less than 1m sec.
- Oscilloscope: Connect an adjustable frequency oscillator to terminal 14 and look for the frequency which provides peak sine waveform on the oscilloscope. Then set for the following conditions.
  1. Input frequency for peak sine wave should be 1.3KHz-2.0KHz.
  2. Peak point level should be between 290mV and 430mV.
(3) VCF–HPF (NE–10500)

VCF: Voltage Controlled Filter
HPF: High Pass Filter

![Diagram of VCF–HPF circuit]

OSCilloscope

Click waveform should be less than 250mV p-p.

Rise and fall of the 100Hz short waveform should be less than 1m sec.

100mV
Sine Wave
1.6 KHz (variable)

![Diagram of sine wave generator]

OSCilloscope

Connect an adjustable frequency oscillator to terminal 14 and look for the frequency which provides peak sine wave form on the oscilloscope. Then set for the following conditions:

1. Input frequency for peak sine wave should be 1.3KHz–2.0KHz.
2. Peak point level should be between 290mV and 430mV

(4) EG–VCF (NE–10800)

EG: Envelope Generator
VCF: Voltage Controlled Filter

![Diagram of EG–VCF circuit]

1. Input frequency for peak sine wave should be 1.3KHz–2.0KHz.
2. Peak point level should be between 290mV and 430mV
1. The following waveform should appear on the oscilloscope when switches 1, 2 and 3 are set to condition 1.

\[ +V_{\text{max}} \]
\[ 0.1V_{\text{max}} \]
\[ 0 \]
\[ -V_{\text{max}} \]

\[ 0.9V_{\text{max}} \]

\[ T1 \]
\[ T2 \]

\[ 0.1 V_{\text{max}} \]

\[ T3 \]

- \[ +V_{\text{max}} = +5V \pm 0.5V \]
- \[ -V_{\text{max}} = -5V \pm 0.5V \]
- \[ T1 = 31 \text{ms} \pm 7\text{ms} \]
- \[ T2 = 180 \text{ms} \pm 40\text{ms} \]
- \[ T3 = 180 \text{ms} \pm 40\text{ms} \]

2. When switch 3 only is set to condition 2 the above waveform should be reversed (with GND as center).

3. When all three switches are in condition 2 the click waveform on the oscilloscope should be less than 50mV p–p.

(5) EG–VCA (NE–10900)

EG: Envelope Generator
VCA: Voltage Control Amplifier

\[ -15V \pm 15\text{mV} \]

\[ +5V \pm 10\text{mV} \]

\[ +10V \pm 20\text{mV} \]

\[ 0.5\text{Hz} \]

Rise and fall time should be less than 1m sec.

How to tune:

1. Set the voltage adjustor of the D.C. power supply to ±15V±0.01V.
2. Set the tuning VR, with center position at panel-2.
3. Adjust the potentiometer VR1 (B-1K) to +4.00V±100μV at the terminal UK on the SM1 circuit board.
4. Adjust the potentiometer VR4 (B-500Ω) to +2.00V±100μV with depress C4 at the terminal UI on the SM1 circuit board.
5. Connect the Earth to the terminal UI, set the offset voltage of the operational amplifier OP3 to less than ±100μV at terminal UO by the potentiometer VR2 on the SM1 circuit board.
